

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email editorial.bmjopen@bmj.com

Competing interests statement:

There are no competing interests. All authors have signed the ICMJE Form for Disclosure of Potential Conflicts of Interest.

ABSTRACT

Objectives

The incidence and mortality of cervical cancer has halved since introduction of the Australian Cervical Screening Program in 1991, involving two-yearly Pap smears from ages 18-69. In 2017, the program will change to primary HPV testing five-yearly for women aged 25-74. This study investigated reasons for opposition to the new screening program within the open-ended comments of an online petition opposing the changes, which received over 70,000 signatures and almost 20,000 comments.

Methods

Content analysis of a random sample of 2000 comments, reflecting 10% of the 19,633 comments posted in February-March 2017.

Results

Nineteen codes were identified, reflecting four themes: 1. valuing women's health and rights; 2. political statements; 3. concerns about healthcare funding cuts; and 4. opposition to specific components of the new screening program. The most prevalent codes were: placing value on women's health (33%); concerns about increasing screening intervals (17%); and opposition to the changes related to personal experiences with cervical cancer or pre-cancerous lesions (15%). Concern about the key change in technology (HPV testing instead of Pap smears) was expressed in less than 3% of comments, and some opposition to the changes from health professionals was noted.

Conclusions

Screening changes were perceived as threatening women's health, as a political policy created by male decision-makers and as a cost-cutting exercise. Many commenters were concerned about increased screening intervals and later screening onset, but little opposition was expressed regarding the testing technology itself. This analysis may inform public education and communication strategies for future changes to both cervical and other screening programs internationally, to pre-emptively address specific concerns about the changes.

STRENGTHS AND LIMITATIONS OF THIS STUDY

- To the best of our knowledge, this is the first study to analyse reasons for opposition to the 2017 Australian cervical screening changes in the wider population since their announcement and public discussion.
- The study is based on 2,000 randomly selected original comments from a sample of almost 20,000, and comments were on average 22 words long, providing sufficient detail to identify reasons for opposition.
- The importance and reach of the petition can be estimated by subsequent responses to it received by the President of the Australian Medical Association, the Australian Government Minister for Health and Australia’s Chief Medical Officer.
- It could be argued that this sample of comments is not representative of the majority of Australian women, but simply a vocal minority. However, this petition was one of the biggest petitions on “Change.org” in 2016 and 2017, indicating high public interest.
- A limitation of this study is the absence of demographic information about petitioners. It is therefore unknown whether this sample represents women or men with lower, average or higher health literacy or educational status. It is likely that the petition attracted responses from persons with a greater interest in health policy or women’s health and may also represent a group with increased personal or family history of cervical cancer.

INTRODUCTION

Cervical cancer is closely related to chronic cervical infection with human papillomavirus (HPV), as well as other contributing factors including cigarette smoking and immunodeficiency (1). High-risk HPV types are a necessary, but not sufficient cause of cervical cancer (1-3). Cervical cancer is amenable to screening, with a long pre-cancerous period (4). Until recently, screening efforts were cytology-based where cells from the cervix were manually collected by trained health professionals, smeared onto a glass slide, stained and analysed by a cytologist (5). Cytology-based screening has proven successful, halving the incidence and mortality of squamous cell cervical cancer in Australia from 1991 to 2013 (6).

Compared to cytology-based screening, recent evidence from large international trials suggest that HPV testing has increased sensitivity to detect high-grade pre-cancerous Cervical Intraepithelial Neoplasia (CIN) or cervical cancer in all age groups (7, 8). As cervical HPV infections are frequently transient and many regress, specificity of the HPV test increases with longer screening interval (8). Furthermore, cytological abnormalities in women younger than 20 years are common and mostly transient, and population based case-control studies show that screening young women does not result in decreased incidence of cervical cancer (9-11).

Based on this evidence, and a greater knowledge of the natural history of HPV and its association with cervical cancer, screening models worldwide are currently changing from cytology to primary HPV DNA testing. In the UK, the National Screening Committee recommended primary HPV testing instead of cytology in January 2016, with an expected screening interval of 5-6 years from age 25 to 64 (12-14). In the USA, the American Cancer Society, U.S. Preventive Services Task Force and American College of Obstetricians and Gynecologists have recommended since 2012 three-yearly cytology from age 21 to 29, then either three-yearly cytology, or five-yearly cytology with HPV co-testing, from age 30 to 65 (15). An increasing number of other countries have also decided or recommended to implement primary HPV screening, including New Zealand, Italy, Sweden and the Netherlands (16). In Australia, the National Cervical Screening Program (NCSP) will be renewed in late 2017 based on an evidence review synthesising the most up-to-date research examining how these developments and greater knowledge can impact the different components of the screening program (i.e. age, screening interval, testing technology) (17). Replacing the current cytology-based cervical screening program, and winding back other components of the program, both HPV-vaccinated and unvaccinated women aged 25 to 69 years will be screened five-yearly using primary HPV testing (5).

In response to the announcement of the renewed NCSP, an online petition was created on the website "Change.org" (18). The petition was initiated in February 2017 by an Australian woman, who stated she was motivated by "concern and worry" after her general practitioner (GP) informed her of the changes, because "[she] didn't know about [the changes] and no one seemed to know about it" (19). The petition attracted over 70,000 signatures and almost 20,000 comments.

The aim of this study was to analyse the petition content of the open-ended comments to identify objections and concerns to the renewed NCSP. This analysis could inform public information and communication strategies for future changes to both cervical and other screening programs internationally, to pre-emptively address specific concerns about the changes.

METHODS

Ethics

The University of Sydney Human Research Ethics Committee reviewed and approved this study [project number 2017/300].

Dataset

The dataset consists of comments posted on the “Change.org” petition ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ between 16th February 2017 and 19th March 2017, inclusively (18). “Change.org” is the most popular online petition website globally, with an open platform available to any member of the public who wants to initiate a petition. The ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ petition was one of the largest Australian online petitions in 2016 and 2017 (by number of supporters) (20). The petition still exists online to this date, but receives minimal signatures and even fewer comments each day. Comments in the dataset were on average 22 words long, ranging from one to 712 words.

Procedure

All 19,633 petition comments were recorded chronologically into a Microsoft Excel spreadsheet. The spreadsheet listed the names of signatories, any original comments, and dates of comment posting. A comment is defined as a piece of text published by an individual in response to a prompt on the petition, “I am signing because...”. The name and location associated with each comment were removed prior to analysis. The comments were randomised, and 10% of the dataset (2000 comments) was randomly selected for analysis.

Analysis

Content analysis is an appropriate research method for scrutinising text data (21). It is also frequently used to analyse social media comments (22, 23). A large body of work has used this method to systematically categorise and quantify content in a dataset into frames and codes (24-26). A code is a pre-defined category which conveys a key component of the comment.

After an initial coding scheme was discussed with all authors and evaluated to have appropriate inter-rater reliability (i.e. Kappa >0.8), it was further refined resulting in 19 categories. Two authors then applied the coding scheme to the final selection of 2000 random comments. Each comment was allocated up to six codes based on its content. HO coded all 2000 comments and RD coded 10% (200) of these comments. Cohen's Kappa of 0.95 was achieved between the two coders, indicating “nearly perfect” agreement (27).

Descriptive statistical analysis was used to assess the frequency of each code. The codes were synthesised into four main themes through discussion with all authors once code frequency had been established.

RESULTS

From a sample of 2000 comments, four main themes emerged from content analysis – 1. valuing women's health and rights; 2. political statements; 3. cost and health care funding; 4. opposition to specific components of the screening program changes (e.g. interval and age of onset of screening). The codes encompassed in each theme are outlined in Table 1 with example quotes. Examples of health professional opposition were also noted.

Qualitative analysis: themes arising in comments

Valuing women's health and rights

The most frequently coded statements (32.6%) implied that the changes to the cervical screening program would de-value and threaten women's health. This was demonstrated by comments such as, "The Pap smear program is important for women's health", "Women matter", "I want to see my daughters and grand-daughters growing up healthy" and "Women have the right to be healthy". Twenty-two percent of commenters argued from personal experience in opposing the changes, because they or somebody they knew had experienced cervical cancer or pre-cancerous cervical lesions. Gender issues were discussed in 7.6% of comments, expressing opposition to men making decisions related to women's health, for example, "If men had periods and needed Pap smears, the tests would be free and be the best in the world".

Political issues

Comments expressed that the current Prime Minister and government were putting women's health at risk (13.6%). Comments included, "This government doesn't care about female reproductive health!", "The government is going too far this time", and, "I expected more from Malcolm Turnbull". Many comments also connected to the concept of gender, expressing the view that these changes would not be occurring if the Australian Prime Minister was a woman, if there were more female members of Parliament or if the Prime Minister had personally known someone affected by cervical cancer. Some comments included, "I think it really reflects that we need more women in decision-making", "If Malcolm [Turnbull] had a cervix these changes wouldn't be happening" and, "Why does the government get to make these decisions, they are mostly men".

Cost and health care funding

Ten percent of commenters believed that the changes to the cervical screening program were a 'cost-cutting exercise', part of 'budget cuts', and that money was being 'taken' from women's health (9.9%). Almost 6% of comments conveyed the importance of maintaining funding for health care in general, for example, "Lives are more important than money". Many expressed the importance of

ensuring that health care and Pap smears should remain affordable and accessible to all women, for example, “Without government funding, some women won’t be able to afford two-yearly testing”. Others argued that while these changes to cervical screening may save money in the short-term, they would increase government costs in the long-term, due to subsequent increased cases of cervical cancer and increased treatment costs. An example includes, “The rates in cervical cancers will undoubtedly rise and end up costing more to treat an easily screened disease” (3.7%).

Opposition to specific changes

Change to the screening interval from two- to five-yearly was the most frequently expressed specific concern (16.7%). Comments included, “Five years between tests is too long to prevent cervical cancer developing to an advanced stage”. Opposition to increased age of first screening invitation was expressed in 9.1% of comments, including, “Women should be tested earlier, not later”, and “25 is too old to start screening”. Notably, only 2.6% of comments expressed hesitation with the HPV test itself. Comments opposing the HPV test included, “limiting the test to only screen for HPV induced cancers will put a greater number of lives at risk”, and discussed that not all cervical cancers were caused by HPV, or that HPV testing is not as thorough as cytology. Almost 5% of comments expressed confidence in the current program and argued that, “if something is not broken, don’t fix it”. Some commenters felt that the changes had not been communicated well, stating, “I think modifications to the testing should be thoroughly consulted across our community” and, “I don’t think the explanation is very clear regarding the changes”.

Health professional opposition

While not occurring frequently enough to be included in the coding scheme, some commenters expressed worry about the changes because their healthcare practitioner (GP or gynaecologist) did not support the changes. Three noteworthy comments were from people who identified themselves as GPs and one from a cytologist who commented that they had seen HPV negative tests with an abnormal Pap smear, that five years was too long an interval and that they had seen cases of cervical cancer in women younger than 25.

Table 1: Frequency of the 19 codes in a random sample of 2000 comments made in response to the petition

| Code description | Example | % |
|--|---|-------------|
| Theme 1: Valuing women's health, gender and women's rights | | 82.4 |
| Valuing women's health and valuing women* | "Every woman matters"; "I have three daughters and I want them to be healthy" | 32.6 |
| Personal or family/friend experience with cervical cancer/pre-cancerous lesion/other cancers | "I have friends who had cancerous and pre-cancerous cells on routine Pap smears BEFORE age 25."; "I had an abnormal Pap smear result at 23, it could've been cancer by 24 and under these new changes I wouldn't have known until I was 25!?" | 22.0 |
| Support for principles of disease prevention/early detection | "Prevention is better than cure!" | 14.1 |
| Gender and males making decisions for/about females and women's health | "Why should a man, who will never get cervical cancer, decide my fate"; "Time to let women have control, choice and safety over their own bodies!" | 7.6 |
| Right/entitlement of women to health care/Pap smears | "As women and taxpayers, we have a right to full health care" | 4.2 |
| A step backwards/policy regression | "This is a huge step backwards for women's rights" | 1.9 |
| Theme 2: Political statements | | 13.6 |
| Political, encompassing: Comments against the Prime Minister, the Liberal party; government as a whole | "The government is going too far this time"; "The amount of money the government waste on things of little to no importance and then to cut back on something as important as this just doesn't make sense" | 13.6 |
| Theme 3: Cost and health care funding concerns | | 19.3 |
| Cost cutting | "This is just another government cost-cutting exercise" | 9.9 |
| Access to health services: health care funding and affordability of tests | "Healthcare should be free in the lucky country"; "It is vital that Pap smears are affordable to all women" | 5.7 |
| Early detection will save money in the long run | "The government think they are saving money with this program, but they don't think of the financial burden on the health care system when there is an increasing in women's cancers as a result" | 3.7 |
| Theme 4: Opposition to specific components of screening program changes | | 36.2 |
| Opposition to extended (5 yearly) screening interval | "Five years is far too long between tests" | 16.7 |
| Concern about missing cancer cases in young women (<25 years of age) | "Young woman under the age of 20 can still get this cancer – 25 is too late!" | 9.1 |
| Concern about missing cancer cases in older women (>74 years of age) or fear of ageism | "After 74 you don't matter?" | 1.6 |
| Preference for the status quo | "I believe the conventional Pap smear screening is a great preventative program" | 4.7 |
| Disagreement with HPV test itself | "Not all cervical cancers are caused by HPV" | 2.6 |
| Sexual activity – age of first invitation to screen should be dependent on age of sexual activity or should generally be earlier due to earlier age of sexual activity | "Pap smears should be available from when sexual activity starts as most young girls these days are having sex very young" | 1.5 |
| No specific reason stated | | 10.4 |
| No reason stated for opposition | "This is important" | 5.7 |
| Emotional response, with no further reason for opposition stated | "This is disgusting"; "I don't want to die" | 3.9 |

*Valuing women's health was a code used in conjunction with other codes 70.2% of the time. The most frequent codes used in conjunction were (in order of frequency): disease prevention/early detection (9.5%), cost cutting (9.4%), politics (8.6%), concern about screening interval (7.7%), right/entitlement (6.0%) and gender (5.5%)

DISCUSSION

This study presents comments and concerns towards the 2017 changes to the Australian NCSP expressed by one of Australia’s largest petitions on “Change.org”. Many comments about women’s health, politics and cost displayed significant misconceptions and misinformation about the rationale for the screening changes. Underpinning most comments in these themes was the idea that under the renewed screening program, an increased number of cervical cancers would be missed or diagnosed at an advanced stage, and that the rationale for changes was based on reducing government healthcare costs. Many commenters voiced concerns about the increased screening interval (from two to five years) and the later age of onset of screening (from 18 or 20 to 25 years of age). We noted a lack of opposition to a change from Pap smears to HPV testing itself. This may be reflective of the information and education material provided to the community in promoting the change, which focused on explaining HPV, or reflective of the lack of understanding of HPV or awareness of this aspect of the changes (28). Another contributing factor to the significant opposition may have been news media coverage, which highlighted safety concerns expressed by opposing government ministers and community members about increased screening intervals and later age of screening onset (19, 29, 30).

Previous studies conducted in Australia prior to the announcement of the changes, have identified women’s concerns about age, intervals and cost-cutting, so these issues could have been addressed in advance through better communication (31-33). A potential for cancer to be missed and a suspicion that an increased screening interval was related to cost, were major concerns for women described in these publications, and are concerns shared by many commenters in our study. Internationally, publications similarly report that while HPV testing is generally accepted by women, longer screening intervals face opposition (34).

Increasingly, these concerns are relayed over social media, as shown by a similar “Change.org” petition in the UK attracting over 300,000 signatures in January 2017 (35). While the petition was focussed on early screening options for symptomatic or high-risk groups, many comments expressed that cervical screening should be available from age 18 for all women. Concerns about increased screening intervals have also been raised by consumers in relation to other cancer types. In the US, recommendations for later starting age of breast cancer screening and prolonged screening intervals, attracted public accusations that the new proposals were politically motivated and ‘anti-woman’ (36, 37).

Opposition to the screening change may reflex status quo bias, and general opposition of people to change (38). Patients and the public often hold the view that ‘more is better’ in medical care (39). This is because many patients have been socialised to fear rare, life-threatening events (40), and hold fatalistic views of cancer (41). Patients also have a widespread enthusiasm for cancer screening, reflecting a lay logic that prevention and early diagnosis is universally beneficial, which is not always the case (42). The relationship between sensitivity and specificity of screening tests is a

difficult concept to communicate, and public health practitioners in the past have mainly focused on sensitivity in promoting screening to the public (43). Much greater efforts are required by public health practitioners to better educate the public about the relative benefits and harms of screening.

There are discrepancies between benefits to the public and benefits to the individual from cancer screening. Personal experience of illness tends to be far more salient for patients than general notions of healthcare spending for society as a whole (44). Public information from government websites regarding the changes have also mentioned the harmful effects of the current Pap smear screening program, for example treatments for abnormal cells which can lead to increases in premature birth (28). While this approach is more effective than discussing collective waste in communicating low-value care to patients, most healthy patients still have difficulty envisioning how screening could be harmful to them (45). Our recommendations for issues to address with patients concerned about the changes are outlined in Table 2.

Table 2: Recommended evidence for healthcare practitioners to address with patients concerned about Cervical Screening Program changes

| Concerns expressed in online petition | Evidence-based responses to concerns |
|--|---|
| Concerns about the sensitivity of HPV testing | HPV testing has increased sensitivity compared to Pap smear testing (8) and so has the potential to detect more cervical abnormalities than cytology-based screening. |
| Concerns about five-yearly screening interval | Increased sensitivity of the new HPV screening test compared to cytology to detect pre-cancerous cervical abnormalities and cervical cancer means that screening can be less frequent while still detecting almost all cervical abnormalities (8). Risk of cervical abnormalities over five years is lower for a HPV negative finding than a negative result from cytology. |
| Concerns about later age of first invitation to screen (25, as opposed to 18 previously) | Most cervical abnormalities in women under the age of 25 tend to regress by themselves, so testing early may lead to unnecessary invasive procedures (10). In women under 25, the harms are likely to outweigh the benefits of screening (e.g. unnecessary invasive procedures that can cause complications) and starting screening at 25 will reduce the number of investigations in this younger age group. Incidence and mortality of cervical cancer in women under 25 is very low and this has not changed since the introduction of the screening program (3). Young women are also offered the HPV vaccination and this is expected to lead to a significant reduction in the risk of cervical cancer in this age group. |

Despite the initial announcement of the changes by the Australian government in April 2014, the changes did not garner significant publicity until 2017. The rollout of the renewed NCSP was planned for May 2017, but has been delayed until December, as a component of the renewed

program, the national cervical cancer register, was not ready for implementation. An implementation phase was to be undertaken which included engaging with the public to assess acceptability and educating clinicians and women about the changes (46). A summary of the Medical Services Advisory Committee application for NCSP changes described limited community consultation through 2012-2013 (47). Feedback was sought from, “clinical service providers, pathology service providers, consumers, professional bodies for health professionals and pathologists, and industry”, but results of these consultations are not described. A 2015 article in the Australian Doctor magazine reported that “very little information has been distributed to GPs [about the changes]” (48). Ideally, clinicians would be an important group to engage and educate the public about cervical screening. The Australian Government website outlining the cervical screening changes encourages women to speak with health professionals about any concerns (28). A 2016 systematic review of 35 publications demonstrated that healthcare provider recommendation was positively correlated with improved screening rates (49).

To the best of our knowledge, this is the first study to analyse reasons for opposition to the 2017 Australian cervical screening changes in the wider population since their announcement and public discussion. The study is based on 2,000 randomly selected original comments from a sample of almost 20,000, and comments were on average 22 words long, providing sufficient detail to identify reasons for opposition. The importance and reach of the petition can be estimated by subsequent responses to it received by the President of the Australian Medical Association, the Australian Government Minister for Health and Australia’s Chief Medical Officer (18).

It could be argued that these commenters are not representative of the majority of Australian women, but simply a vocal minority. However, this petition was one of the biggest petitions on “Change.org” in 2016 and 2017, indicating high public interest. Evidence supports that public information exposure through social media has tangible impacts on health practices (50). Nevertheless, a limitation of this study is the absence of demographic information about petitioners. It is therefore unknown whether this sample represents women or men with lower, average or higher health literacy or educational status. If this is the case, more appropriate information targeting this demographic is required. However, it is more likely that the petition attracted responses from persons with a greater interest in health policy or women’s health and may also represent a group with increased personal or family history of cervical cancer (36). It should also be noted that several comments were from health care providers opposed to the changes, which may indicate that concern is spread across socio-economic and educational status, and that there is a need to address both professional and public concerns.

This study has practical and international implications for informing the rollout of future screening program changes. It highlights the importance of effective communication to the public of changes which involve ‘winding back’ screening programs. Communication must acknowledge emotions involved in this screening wind-back, and should anticipate the public’s known concerns and must

engage them in the decision-making process of screening changes. If the public is “misinformed and misguided”, as suggested by the President of the Australian Medical Association in opposing the renewed cervical screening program, then this could be seen as a reflection of a failure to effectively communicate the changes and their rationale (18). GPs, gynaecologists and other health-care professionals who will discuss cervical screening with patients should be aware of public concern, and be prepared to discuss the reasons for the older starting age and longer screening intervals, not just the change in testing technology.

Competing interests statement:

There are no competing interests. All authors have signed the ICMJE Form for Disclosure of Potential Conflicts of Interest.

ABSTRACT

Objectives

The incidence and mortality of cervical cancer has halved since introduction of the Australian Cervical Screening Program in 1991, involving two-yearly Pap smears from ages 18-69. In 2017, the program will change to primary HPV testing five-yearly for women aged 25-74. This study investigated reasons for opposition to the new screening program within the open-ended comments of an online petition, 'Stop May 1st Changes to Pap Smears - Save Women's Lives', opposing the changes, which received over 70,000 signatures and almost 20,000 comments.

Methods

Content analysis of a random sample of 2000 comments, reflecting 10% of the 19,633 comments posted in February-March 2017.

Results

Nineteen codes were identified, reflecting four themes: 1. valuing women's health and rights; 2. political statements; 3. concerns about healthcare funding cuts; and 4. opposition to specific components of the new screening program. The most prevalent codes were: placing value on women's health (33%); concerns about increasing screening intervals (17%); and opposition to the changes related to personal experiences with cervical cancer or pre-cancerous lesions (15%). Concern about the key change in technology (HPV testing instead of Pap smears) was expressed in less than 3% of comments, and some opposition to the changes from health professionals was noted.

Conclusions

Screening changes within this selected group were perceived as threatening women's health, as a political policy created by male decision-makers and as a cost-cutting exercise. Many commenters were concerned about increased screening intervals and later screening onset, but little opposition was expressed regarding the testing technology itself. This analysis may inform public education and communication strategies for future changes to both cervical and other screening programs internationally, to pre-emptively address specific concerns about the changes.

STRENGTHS AND LIMITATIONS OF THIS STUDY

- To the best of our knowledge, this is the first study to analyse reasons for opposition to the 2017 Australian cervical screening changes in the wider population since their announcement and public discussion.
- The study is based on 2,000 randomly selected original comments from a sample of almost 20,000, and comments were on average 22 words long, providing sufficient detail to identify reasons for opposition.
- Responses to the petition by the President of the Australian Medical Association, the Australian Government Minister for Health and Australia’s Chief Medical Officer indicate the significance and size of the petition as worthy of comment by key stakeholders in this policy issue. However, it is also plausible that their response was simply motivated because the concerns raised in the petition were unfounded.
- It could be argued that this sample of comments is not representative of the majority of Australian women, but simply a vocal minority. However, this petition was one of the biggest petitions on “Change.org” in 2016 and 2017, indicating high public interest.
- A limitation of this study is the absence of demographic information about petitioners. It is therefore unknown whether this sample represents women or men with lower, average or higher health literacy or educational status. It is likely that the petition attracted responses from persons with a greater interest in health policy or women’s health and may also represent a group with increased personal or family history of cervical cancer.

INTRODUCTION

Cervical cancer is strongly associated with chronic cervical infection with oncogenic or “high risk” human papillomavirus (HPV) types. Other contributing factors including cigarette smoking and immunodeficiency (1). High-risk HPV types are a necessary, but not sufficient cause of cervical cancer (1-3). Cervical cancer is amenable to screening, with a long pre-cancerous period (4). Until recently, screening efforts were cytology-based where cells from the cervix were manually collected by trained health professionals, smeared onto a glass slide, stained and analysed by a cytologist (5). Cytology-based screening has proven successful, halving the incidence and mortality of squamous cell cervical cancer in Australia from 1991 to 2002, where it remained steady until 2012 when it rose slightly (6).

Compared to cytology-based screening, recent evidence from large international trials shows that HPV testing has increased sensitivity to detect high-grade pre-cancerous Cervical Intraepithelial Neoplasia (CIN) or cervical cancer in all age groups (7, 8). As cervical HPV infections are frequently transient and many regress, specificity of the HPV test increases with longer screening interval (8). Furthermore, cytological abnormalities in women younger than 25 years are common and mostly transient, and population based case-control studies show that screening young women does not result in decreased incidence of cervical cancer (9-11).

Based on this evidence, and a greater knowledge of the natural history of HPV and its association with cervical cancer, screening models worldwide are currently changing from cytology to primary HPV DNA testing. In the UK, the National Screening Committee recommended primary HPV testing instead of cytology in January 2016, with an expected screening interval of 5-6 years from age 25 to 64 (12-14). In the USA, the American Cancer Society, U.S. Preventive Services Task Force and American College of Obstetricians and Gynecologists have recommended since 2012 three-yearly cytology from age 21 to 29, then either three-yearly cytology, or five-yearly cytology with HPV co-testing, from age 30 to 65 (15). Other countries have also decided to recommend implementation of primary HPV screening, including New Zealand, Italy, Sweden and the Netherlands (16). In Australia, the National Cervical Screening Program (NCSP) will be renewed in late 2017 based on an evidence review synthesising the most up-to-date research examining how these developments and greater knowledge can impact the different components of the screening program (i.e. age, screening interval, testing technology) (17). Replacing the current cytology-based cervical screening program, both HPV-vaccinated and unvaccinated women aged 25 to 74 years will be screened five-yearly using primary HPV testing (5).

In response to the announcement of the renewed NCSP, an online petition was created on the website “Change.org” (18). The petition was initiated in February 2017 by an Australian woman, who stated she was motivated by “concern and worry” after her general practitioner (GP) informed her of the changes, because “[she] didn’t know about [the changes] and no one seemed to know about it” (19). The petition attracted over 70,000 signatures and almost 20,000 comments.

The aim of this study was to analyse the petition content of the open-ended comments to identify objections and concerns to the renewed NCSP. A significant challenge is how to present a new screening program with major changes so that confidence in the current program is not undermined. This analysis could help inform public information and communication strategies for future changes to cervical screening programs internationally, by pre-emptively addressing specific concerns about the changes.

METHODS

Ethics

The University of Sydney Human Research Ethics Committee reviewed and approved this study [project number 2017/300].

Dataset

The dataset consists of comments posted on the “Change.org” petition ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ (Supplement 1) between 16th February 2017 and 19th March 2017, inclusively (18). “Change.org” is the most popular online petition website globally, with an open platform available to any member of the public who wants to initiate a petition. The ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ petition was one of the largest Australian online petitions in 2016 and 2017 (by number of supporters) (20). The petition received exponentially fewer comments each day after the 20th of February 2017, but still exists online to this date, receiving minimal signatures and even fewer comments each day. Comments in the dataset were on average 22 words long, ranging from one to 712 words.

Procedure

All 19,633 petition comments were recorded chronologically into a Microsoft Excel spreadsheet. The spreadsheet listed the names of signatories, any original comments, and dates of comment posting. A comment is defined as a piece of text published by an individual in response to a prompt on the petition, “I am signing because...”. The name and location associated with each comment were removed prior to analysis. The comments were randomised with a random number generator in Microsoft Excel and sorting into ascending order, and 10% of the dataset (2000 comments) was randomly selected for analysis.

Analysis

Content analysis combines both qualitative and quantitative methods, allowing both the frequency of categories to be reported, as well as the content (21). Content analysis is an appropriate research method for scrutinising text data (22). It is also frequently used to analyse social media comments (23, 24). A large body of work has used this method to systematically categorise and quantify content in a dataset into frames and codes (25-27). A code is a pre-defined category which conveys a key component of the comment.

The analysis represents the perspective of psychological health researchers and epidemiologists. HO first became familiar with the content of the comments by reading through the comments and making note of recurring themes. After an initial coding scheme was discussed with all authors and evaluated to have appropriate inter-rater reliability (i.e. Kappa >0.8), it was further refined resulting in 19 categories. Two authors then applied the coding scheme to the final selection of 2000 random comments. Each comment was allocated up to six codes based on its content. HO coded all 2000 comments and RD coded 10% (200) of these comments. Cohen's Kappa was calculated using IBM SPSS Statistics, version 21. Cohen's Kappa of 0.95 was achieved between the two coders, indicating "nearly perfect" agreement (28).

Descriptive statistical analysis was used to assess the frequency of each code. The codes were synthesised into four main themes through discussion with all authors once code frequency had been established.

RESULTS

From a sample of 2000 comments, four main themes emerged from content analysis – 1. valuing women's health and rights; 2. political statements; 3. cost and health care funding; 4. opposition to specific components of the screening program changes (e.g. interval and age of onset of screening). The codes encompassed in each theme are outlined in Table 1 with example quotes. Examples of health professional opposition were also noted.

Qualitative analysis: themes arising in comments

Valuing women's health and rights

The most frequently coded statements (32.6%) implied that the changes to the cervical screening program would de-value and threaten women's health. This was demonstrated by comments such as, "The Pap smear program is important for women's health", "Women matter", "I want to see my daughters and grand-daughters growing up healthy" and "Women have the right to be healthy". Twenty-two percent of commenters argued from personal experience in opposing the changes, because they or somebody they knew had experienced cervical cancer or pre-cancerous cervical lesions. Gender issues were discussed in 7.6% of comments, expressing opposition to men making decisions related to women's health, for example, "If men had periods and needed Pap smears, the tests would be free and be the best in the world".

Political issues

Comments expressed that the current Prime Minister and government were putting women's health at risk (13.6%). Comments included, "This government doesn't care about female reproductive health!", "The government is going too far this time", and, "I expected more from Malcolm Turnbull". Many comments also connected to the concept of gender, expressing the view that these changes would not be occurring if the Australian Prime Minister was a woman, if there were more female

members of Parliament or if the Prime Minister had personally known someone affected by cervical cancer. Some comments included, “I think it really reflects that we need more women in decision-making”, “If Malcolm [Turnbull] had a cervix these changes wouldn’t be happening” and, “Why does the government get to make these decisions, they are mostly men”.

Cost and health care funding

Ten percent of commenters believed that the changes to the cervical screening program were a ‘cost-cutting exercise’, part of ‘budget cuts’, and that money was being ‘taken’ from women’s health (9.9%). Almost 6% of comments conveyed the importance of maintaining funding for health care in general, for example, “Lives are more important than money”. Many expressed the importance of ensuring that health care and Pap smears should remain affordable and accessible to all women, for example, “Without government funding, some women won’t be able to afford two-yearly testing”. Others argued that while these changes to cervical screening may save money in the short-term, they would increase government costs in the long-term, due to subsequent increased cases of cervical cancer and increased treatment costs. An example includes, “The rates in cervical cancers will undoubtedly rise and end up costing more to treat an easily screened disease” (3.7%).

Opposition to specific changes

Change to the screening interval from two- to five-yearly was the most frequently expressed specific concern (16.7%). Comments included, “Five years between tests is too long to prevent cervical cancer developing to an advanced stage”. Opposition to increased age of first screening invitation was expressed in 9.1% of comments, including, “Women should be tested earlier, not later”, and “25 is too old to start screening”. Notably, only 2.6% of comments expressed hesitation with the HPV test itself. Comments opposing the HPV test included, “limiting the test to only screen for HPV induced cancers will put a greater number of lives at risk”, and discussed that not all cervical cancers were caused by HPV, or that HPV testing is not as thorough as cytology. Just under five percent of comments expressed confidence in the current program and argued that, “if something is not broken, don’t fix it”. Some commenters felt that the changes had not been communicated well, stating, “I think modifications to the testing should be thoroughly consulted across our community” and, “I don’t think the explanation is very clear regarding the changes”.

Health professional opposition

While not occurring frequently enough to be included in the coding scheme, some commenters expressed worry about the changes because their healthcare practitioner (GP or gynaecologist) did not support the changes. Three noteworthy comments were from people who identified themselves as GPs and one from a cytologist who commented that they had seen HPV negative tests with an abnormal Pap smear, that five years was too long an interval and that they had seen cases of cervical cancer in women younger than 25.

Table 1: Frequency of the 19 codes in a random sample of 2000 comments made in response to the petition

| Code description | Example | % |
|--|---|-------------|
| Theme 1: Valuing women's health, gender and women's rights | | 82.4 |
| Valuing women's health and valuing women* | "Every woman matters"; "I have three daughters and I want them to be healthy" | 32.6 |
| Personal or family/friend experience with cervical cancer/pre-cancerous lesion/other cancers | "I have friends who had cancerous and pre-cancerous cells on routine Pap smears BEFORE age 25."; "I had an abnormal Pap smear result at 23, it could've been cancer by 24 and under these new changes I wouldn't have known until I was 25!?" | 22.0 |
| Support for principles of disease prevention/early detection | "Prevention is better than cure!" | 14.1 |
| Gender and males making decisions for/about females and women's health | "Why should a man, who will never get cervical cancer, decide my fate"; "Time to let women have control, choice and safety over their own bodies!" | 7.6 |
| Right/entitlement of women to health care/Pap smears | "As women and taxpayers, we have a right to full health care" | 4.2 |
| A step backwards/policy regression | "This is a huge step backwards for women's rights" | 1.9 |
| Theme 2: Political statements | | 13.6 |
| Political, encompassing: Comments against the Prime Minister, the Liberal party; government as a whole | "The government is going too far this time"; "The amount of money the government waste on things of little to no importance and then to cut back on something as important as this just doesn't make sense" | 13.6 |
| Theme 3: Cost and health care funding concerns | | 19.3 |
| Cost cutting | "This is just another government cost-cutting exercise" | 9.9 |
| Access to health services: health care funding and affordability of tests | "Healthcare should be free in the lucky country"; "It is vital that Pap smears are affordable to all women" | 5.7 |
| Early detection will save money in the long run | "The government think they are saving money with this program, but they don't think of the financial burden on the health care system when there is an increasing in women's cancers as a result" | 3.7 |
| Theme 4: Opposition to specific components of screening program changes | | 36.2 |
| Opposition to extended (5 yearly) screening interval | "Five years is far too long between tests" | 16.7 |
| Concern about missing cancer cases in young women (<25 years of age) | "Young woman under the age of 20 can still get this cancer – 25 is too late!" | 9.1 |
| Concern about missing cancer cases in older women (>74 years of age) or fear of ageism | "After 74 you don't matter?" | 1.6 |
| Preference for the status quo | "I believe the conventional Pap smear screening is a great preventative program" | 4.7 |
| Disagreement with HPV test itself | "Not all cervical cancers are caused by HPV" | 2.6 |
| Sexual activity – age of first invitation to screen should be dependent on age of sexual activity or should generally be earlier due to earlier age of sexual activity | "Pap smears should be available from when sexual activity starts as most young girls these days are having sex very young" | 1.5 |
| No specific reason stated | | 10.4 |
| No reason stated for opposition | "This is important" | 5.7 |
| Emotional response, with no further reason for opposition stated | "This is disgusting"; "I don't want to die" | 3.9 |

*Valuing women's health was a code used in conjunction with other codes 70.2% of the time. The most frequent codes used in conjunction were (in order of frequency): disease prevention/early detection (9.5%), cost cutting (9.4%), politics (8.6%), concern about screening interval (7.7%), right/entitlement (6.0%) and gender (5.5%)

DISCUSSION

This study presents comments and concerns about the 2017 changes to the Australian NCSP expressed by one of Australia's largest petitions on "Change.org". Many comments about women's health, politics and cost displayed significant misconceptions and misinformation about the rationale for the screening changes. Underpinning most comments in these themes was the idea that under the renewed screening program, an increased number of cervical cancers would be missed or diagnosed at an advanced stage, and that the rationale for changes was based on reducing government healthcare costs. Many commenters voiced concerns about the increased screening interval (from two to five years) and the later age of onset of screening (from 18 or 20 to 25 years of age). We noted a lack of opposition to a change from Pap smears to HPV testing itself. This may be reflective of the information and education material provided to the community in promoting the change, which focused on explaining HPV, or reflective of the lack of understanding of HPV or awareness of this aspect of the changes (29). Another contributing factor to the significant opposition may have been news media coverage, which highlighted safety concerns expressed by opposing government ministers and community members about increased screening intervals and later age of screening onset (19, 30, 31).

Previous studies conducted in Australia prior to the announcement of the changes, have identified women's concerns about age, intervals and cost-cutting, so these issues could have been addressed in advance through better communication (32-34). A potential for cancer to be missed and a suspicion that an increased screening interval was related to cost, were major concerns for women described in these publications, and are concerns shared by many commenters in our study. Internationally, publications similarly report that while HPV testing is generally accepted by women, longer screening intervals face opposition (35).

Increasingly, these concerns are relayed over social media, as shown by a similar "Change.org" petition in the UK attracting over 300,000 signatures in January 2017 (36). While the petition was focussed on early screening options for symptomatic or high-risk groups, many comments expressed that cervical screening should be available from age 18 for all women. Concerns about increased screening intervals have also been raised by consumers in relation to other cancer types. In the US, recommendations for later starting age of breast cancer screening and prolonged screening intervals, attracted public accusations that the new proposals were politically motivated and 'anti-woman' (37, 38).

Opposition to the screening change may reflect status quo bias, and general opposition of people to change (39). Patients and the public often hold the view that 'more is better' in medical care (40). This is because many patients have been socialised to fear rare, life-threatening events (41), and hold fatalistic views of cancer (42). Patients also have a widespread enthusiasm for cancer

screening, reflecting a lay logic that prevention and early diagnosis is universally beneficial, which is not always the case (43). The relationship between sensitivity and specificity of screening tests is a difficult concept to communicate, and public health practitioners in the past have mainly focused on sensitivity in promoting screening to the public (44). We believe much greater efforts are required by public health practitioners to better educate the public about the relative benefits and harms of screening.

There are discrepancies between benefits to the public and benefits to the individual from cancer screening. Personal experience of illness tends to be far more salient for patients than general notions of healthcare spending for society as a whole (45). Public information from government websites regarding the changes have also mentioned the harmful effects of the current Pap smear screening program, for example treatments for abnormal cells which can lead to increases in premature birth (29). While this approach is more effective than discussing collective waste in communicating low-value care to patients, most healthy patients still have difficulty envisioning how screening could be harmful to them (46). Our recommendations for issues to address with patients concerned about the changes are outlined in Table 2.

Table 2: Recommended evidence for healthcare practitioners to address with patients concerned about Cervical Screening Program changes

| Concerns expressed in online petition | Evidence-based responses to concerns |
|--|---|
| Concerns about the sensitivity of HPV testing | HPV testing has increased sensitivity compared to Pap smear testing (8) and so has the potential to detect more cervical abnormalities than cytology-based screening. |
| Concerns about five-yearly screening interval | Increased sensitivity of the new HPV screening test compared to cytology to detect pre-cancerous cervical abnormalities and cervical cancer means that screening can be less frequent while still detecting almost all cervical abnormalities (8). Risk of cervical abnormalities over five years is lower for a HPV negative finding than a negative result from cytology over a two or three year interval. HPV testing can identify women at risk often before cell changes occur, whereas Pap smears detect changes to cervical cells after they have occurred. |
| Concerns about later age of first invitation to screen (25, as opposed to 18 previously) | Most cervical abnormalities in women under the age of 25 tend to regress by themselves, so testing early may lead to unnecessary invasive procedures (10). In women under 25, the harms are likely to outweigh the benefits of screening (e.g. unnecessary invasive procedures that can cause complications) and starting screening at 25 will reduce the number of investigations in this younger age group. Incidence and mortality of cervical cancer in women under 25 is very low and this has not changed since the introduction of the screening program (3). Young women are also offered the HPV vaccination and this is expected to lead to a significant reduction in the risk of cervical |

|--|---------------------------|
| | cancer in this age group. |
|--|---------------------------|

Despite the initial announcement of the changes by the Australian government in April 2014, the changes did not garner significant publicity until 2017. The rollout of the renewed NCSP was planned for May 2017, but has been delayed until December, as a component of the renewed program, the National Cancer Screening Register, was not ready for implementation. An implementation phase was to be undertaken which included engaging with the public to assess acceptability and educating clinicians and women about the changes (47). A summary of the Medical Services Advisory Committee application for NCSP changes described limited community consultation through 2012-2013 (48). Feedback was sought from, “clinical service providers, pathology service providers, consumers, professional bodies for health professionals and pathologists, and industry”, but results of these consultations are not described. While limited education has been provided to GPs through research initiatives such as the Compass trial in Victoria (49), and online education modules for clinicians were released in late 2017 (50), a 2015 article in the Australian Doctor magazine reported that “very little information has been distributed to GPs [about the changes]” (51). Ideally, clinicians would be an important group to engage and educate the public about cervical screening. The Australian Government website outlining the cervical screening changes encourages women to speak with health professionals about any concerns (29). A 2016 systematic review of 35 publications demonstrated that healthcare provider recommendation was positively correlated with improved screening rates (52).

To the best of our knowledge, this is the first study to analyse reasons in the wider population for opposition to the 2017 Australian cervical screening changes since their announcement and public discussion. The study is based on 2,000 randomly selected original comments from a sample of almost 20,000, and comments were on average 22 words long, providing sufficient detail to identify reasons for opposition. The importance and reach of the petition can be estimated by subsequent responses to it from the President of the Australian Medical Association, the Australian Government Minister for Health and Australia’s Chief Medical Officer (18).

It could be argued that these commenters are not representative of the majority of Australian women, but simply a vocal minority. However, this petition was one of the biggest petitions on “Change.org” in 2016 and 2017, indicating high public interest. Evidence supports the notion that public information exposure through social media has tangible impacts on health practices (53). Although the comments may not be representative of the majority of Australian women, we cannot disregard the impact that public opposition such as this can have on changes to public policy, for example where the recommendations for changing the US breast screening program received such a backlash that the US Preventive Services Task Force was forced to reword the recommendations (37, 38). The strong views of a minority of vocal community members can be very powerful in the area of cancer screening.

Nevertheless, a limitation of this study is the absence of demographic information about petitioners. It is therefore unknown whether this sample represents women or men with lower, average or higher health literacy or educational status. If this is the case, more appropriate information targeting this demographic is required. However, it is more likely that the petition attracted responses from persons with a greater interest in health policy or women's health and may also represent a group with increased personal or family history of cervical cancer (37). It should also be noted that several comments were from health care providers opposed to the changes, which may indicate that concern is spread across socio-economic and educational status, and that there is a need to address both professional and public concerns.

This study has practical and international implications for informing the significant challenge of rolling out future screening program changes. It highlights the importance of effective communication to the public, of changes which involve longer screening intervals, later age of first invitation to screen and change in screening technology. Developing an understanding of the public's awareness of the benefits and harms of screening is crucial in the development of information about these changes. Communication must acknowledge emotions involved in this screening change, should anticipate the public's known concerns, and must engage them in the decision-making process of screening changes. Future research will explore the optimum time to involve the public in screening policy. If the public is "misinformed and misguided", as suggested by the President of the Australian Medical Association in opposing the renewed cervical screening program, then this could be seen as a reflection of a failure to effectively communicate the changes and their rationale (18). GPs, gynaecologists and other health-care professionals who will discuss cervical screening with patients should be aware of public concern, and be prepared to discuss the reasons for the older starting age and longer screening intervals because of the change in testing technology.

Supplement – The petition - Stop May 1st Changes to Pap Smears - Save Women's Lives

Early detection and regular pap smears are key to preventing and treating women with cervical cancer.

This effects you. Whether you are a woman or you have a mother, sister, aunty or grandmother. May 1st will see changes that will put women's lives at risk but save the government money.

As of May 1st the following changes will be implemented to women's Pap Smears:

"-women will be invited when they are due to participate via the National Cancer Screening Register

-the time between tests will change from two to five years

-the age at which screening starts will increase from 18 years to 25 years

-women aged 70 to 74 years will be invited to have an exit test.

The new program will commence from 1 May 2017 when the new Cervical Screening Test will become available on the Medicare Benefits Schedule. Until this time, women aged between 18 and 69 years who have ever been sexually active, should continue to have Pap test when due."

The government run website states that:

"Based on new evidence and better technology, the National Cervical Screening Program will change from 1 May 2017 to improve early detection and save more lives."

How can there be early detection when the time between pap smears has been extended by 3 years? And the age to begin pap smears is raised to the age of 25?

If you think you are immune to cervical cancer because you are too young - think again. Today the nurse at my doctors surgery told me that she did the pap smear of a young women in her early 20s who was diagnosed with cervical cancer. The cervical cancer she had was a type that will NOT be tested for after May 1. It was NOT caused by the HPV Virus. This young girl was forced to return from an overseas holiday for immediate treatment and died within 6 months.

Prior to May 1 the website advises:

"It is very important that women continue to participate in the current two yearly Pap test program to ensure they are not at risk of developing cervical cancer.

Pap tests have already halved the incidence and mortality from cervical cancer since the introduction of the National Cervical Screening Program in 1991.

Women will be due for the first Cervical Screening Test two years after their last Pap test."

So why would the change be increased from every 2 to 5 years if it is still important to have this done?

The next extremely worrying point of the new smear will be the following:

"The new Cervical Screening Test detects human papillomavirus (HPV) infection, which is the first step in developing cervical cancer.

The procedure for collecting the sample for HPV testing is the same as the procedure for having a Pap smear. A Health Care Professional will still take a small sample of cells from the woman's cervix. The sample will be sent to a pathology laboratory for examination.

While the current Pap test can detect abnormal cell changes, the new Cervical Screening Test will detect the HPV infection that can cause the abnormal cell changes, prior to the development of cancer.

Persistent HPV infections can cause abnormal cell changes that may lead to cervical cancer.

However, this usually takes a long time, often more than 10 years."

This means that ONLY HPV caused cervical cancer will be detected. HPV infection only account for 80-85% of Cervical cancers.

WHAT ABOUT THE OTHER 15%?

Some of the reasoning behind the changes are:

" -cervical cancer in young women is rare (in both HPV vaccinated and unvaccinated women)

-despite screening women younger than 25 years of age for over 20 years there has been no change to the rates of cervical cancer or rates of death from cervical cancer in this age group

-investigating and treating common cervical abnormalities in young women that would usually resolve by themselves can increase the risk of pregnancy complications later in life

-the HPV vaccination has already been shown to reduce cervical abnormalities among women younger than 25 years of age and, in contrast to screening, is ultimately expected to reduce cervical cancer in this age group."

Woman have now become a statistic - stating that it is rare in younger woman is not good enough.

It still happens and early detection and prevention is better than a cure.

Please see petition updates and responses. Dr Michael Gannon has responded to the petition.

Consolidated criteria for reporting qualitative studies (COREQ): 32-item checklist

Developed from:
Tong A, Sainsbury P, Craig J. Consolidated criteria for reporting qualitative research (COREQ): a 32-item checklist for interviews and focus groups. *International Journal for Quality in Health Care*. 2007. Volume 19, Number 6: pp. 349 – 357

| No. Item | Guide questions/description | Reported on Page # |
|--|--|---|
| Domain 1: Research team and reflexivity | | |
| <i>Personal Characteristics</i> | | |
| 1. Inter viewer/facilitator | Which author/s conducted the inter view or focus group? | Page 6 |
| 2. Credentials | What were the researcher’s credentials? E.g. PhD, MD | Page 6 |
| 3. Occupation | What was their occupation at the time of the study? | Page 6 |
| 4. Gender | Was the researcher male or female? | N/A |
| 5. Experience and training | What experience or training did the researcher have? | Page 6 |
| <i>Relationship with participants</i> | | |
| 6. Relationship established | Was a relationship established prior to study commencement? | N/A – no relationship between participants and researchers. |
| 7. Participant knowledge of the interviewer | What did the participants know about the researcher? e.g. personal goals, reasons for doing the research | N/A – no relationship between participants and researchers. |
| 8. Interviewer characteristics | What characteristics were reported about the inter viewer/facilitator? e.g. Bias, assumptions, reasons and interests in the research topic | N/A – no interviews conducted |

| | | |
|--|--|-------------------------------------|
| Domain 2: study design | | |
| <i>Theoretical framework</i> | | |
| 9. Methodological orientation and Theory | What methodological orientation was stated to underpin the study? e.g. grounded theory, discourse analysis, ethnography, phenomenology, content analysis | Page 5 and 6 |
| <i>Participant selection</i> | | |
| 10. Sampling | How were participants selected? e.g. purposive, convenience, consecutive, snowball | Page 5 |
| 11. Method of approach | How were participants approached? e.g. face-to-face, telephone, mail, email | Page 5 |
| 12. Sample size | How many participants were in the study? | Page 5 |
| 13. Non-participation | How many people refused to participate or dropped out? Reasons? | N/A – no non-participants |
| <i>Setting</i> | | |
| 14. Setting of data collection | Where was the data collected? e.g. home, clinic, workplace | Page 5 |
| 15. Presence of non-participants | Was anyone else present besides the participants and researchers? | N/A – using existing online dataset |

Competing interests statement:

There are no competing interests. All authors have signed the ICMJE Form for Disclosure of Potential Conflicts of Interest.

ABSTRACT

Objectives

The incidence and mortality of cervical cancer has halved since introduction of the Australian Cervical Screening Program in 1991, involving two-yearly Pap smears from ages 18-69. In 2017, the program changed to primary HPV testing five-yearly for women aged 25-74. This study investigated reasons for opposition to the renewed screening program within the open-ended comments of an online petition, 'Stop May 1st Changes to Pap Smears - Save Women's Lives', opposing the changes, which received over 70,000 signatures and almost 20,000 comments.

Methods

Content analysis of a random sample of 2000 comments, reflecting 10% of the 19,633 comments posted in February-March 2017.

Results

Nineteen codes were identified, reflecting four themes: 1. valuing women's health and rights; 2. political statements; 3. concerns about healthcare funding cuts; and 4. opposition to specific components of the new screening program. The most prevalent codes were: placing value on women's health (33%); concerns about increasing screening intervals (17%); and opposition to the changes related to personal experiences with cervical cancer or pre-cancerous lesions (15%). Concern about the key change in technology (HPV testing instead of Pap smears) was expressed in less than 3% of comments, and some opposition to the changes from health professionals was noted.

Conclusions

Screening changes within this selected group were perceived as threatening women's health, as a political policy created by male decision-makers and as a cost-cutting exercise. Many commenters were concerned about increased screening intervals and later screening onset, but little opposition was expressed regarding the testing technology itself. This analysis may inform public education and communication strategies for future changes to cervical screening programs internationally, to pre-emptively address specific concerns about the changes.

STRENGTHS AND LIMITATIONS OF THIS STUDY

- This is the first study to analyse reasons for opposition to the 2017 Australian cervical screening changes in the wider population.
- The study analysed 2,000 comments (average 22 words long) from a sample of almost 20,000, providing sufficient detail to identify reasons for opposition.
- Responses to the petition by key stakeholders in this policy issue indicate the significance and size of the petition, and may have been motivated by concerns that claims in the petition were unfounded.
- We cannot determine whether the petition comments reflect the views of most Australian women, however, this petition was one of the biggest petitions on “Change.org” in 2016-17, indicating high public interest.
- A limitation of this study is the absence of demographic information about petitioners, so it is unknown if the sample is representative of women eligible for screening.

INTRODUCTION

Cervical cancer is strongly associated with chronic cervical infection with oncogenic or “high risk” human papillomavirus (HPV) types. Other contributing factors including cigarette smoking and immunodeficiency (1). High-risk HPV types are a necessary, but not sufficient cause of cervical cancer (1-3). Cervical cancer is amenable to screening, with a long pre-cancerous period (4). Until recently, screening efforts were cytology-based where cells from the cervix were manually collected by trained health professionals, smeared onto a glass slide, stained and analysed by a cytologist (5). Cytology-based screening has proven successful, halving the incidence and mortality of squamous cell cervical cancer in Australia from 1991 to 2002, where it remained steady until 2012 when it rose slightly (6).

Compared to cytology-based screening, recent evidence from large international trials shows that HPV testing has increased sensitivity to detect high-grade pre-cancerous Cervical Intraepithelial Neoplasia (CIN) or cervical cancer in all age groups (7, 8). As cervical HPV infections are frequently transient and many regress, specificity of the HPV test increases with longer screening interval (8). Furthermore, cytological abnormalities in women younger than 25 years are common and mostly transient, and population based case-control studies show that screening young women does not result in decreased incidence of cervical cancer (9-11).

Based on this evidence, and a greater knowledge of the natural history of HPV and its association with cervical cancer, screening models worldwide are currently changing from cytology to primary HPV DNA testing. In the UK, the National Screening Committee recommended primary HPV testing instead of cytology in January 2016, with an expected screening interval of 5-6 years from age 25 to 64 (12-14). In the USA, the American Cancer Society, U.S. Preventive Services Task Force and American College of Obstetricians and Gynecologists have recommended three-yearly cytology from age 21 to 29, then either three-yearly cytology alone, or five-yearly HPV testing, from age 30 to 65 (15). Other countries have also decided to recommend, or have already implemented primary HPV screening, including New Zealand, Italy, Sweden and the Netherlands (16). In Australia, the National Cervical Screening Program (NCSP) was renewed in late 2017 based on an evidence review synthesising the most up-to-date research examining how these developments and greater knowledge can impact the different components of the screening program (i.e. age, screening interval, testing technology) (17). Replacing the current two-yearly cytology-based cervical screening program from ages 18 to 69, both HPV-vaccinated and unvaccinated women aged 25 to 74 years will now be screened five-yearly using primary HPV testing (5).

In response to the announcement of the renewed NCSP, an online petition was created on the website “Change.org” (18). The petition was initiated in February 2017 by an Australian woman, who stated she was motivated by “concern and worry” after her general practitioner (GP) informed her of the changes, because “[she] didn’t know about [the changes] and no one seemed to know about it” (19). The petition attracted over 70,000 signatures and almost 20,000 comments.

The aim of this study was to analyse the petition content of the open-ended comments to identify themes in the objections and concerns to the renewed NCSP. This analysis could help inform public information and communication strategies for future changes to cervical screening programs internationally, by pre-emptively addressing specific concerns about the changes.

METHODS

Ethics

The University of Sydney Human Research Ethics Committee reviewed and approved this study [project number 2017/300].

Dataset

The dataset consists of comments posted on the “Change.org” petition ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ (Supplement 1) between 16th February 2017 and 19th March 2017, inclusively (18). “Change.org” is the most popular online petition website globally, with an open platform available to any member of the public who wants to initiate a petition. The ‘Stop May 1st Changes to Pap Smears - Save Women's Lives’ petition was one of the largest Australian online petitions in 2016 and 2017 (by number of supporters) (20). The petition received exponentially fewer comments each day after the 20th of February 2017, but still exists online to this date, receiving minimal signatures and even fewer comments each day. Comments in the dataset were on average 22 words long, ranging from one to 712 words.

Procedure

All 19,633 petition comments were recorded chronologically into a Microsoft Excel spreadsheet. The spreadsheet listed the names of signatories, any original comments, and dates of comment posting. A comment is defined as a piece of text published by an individual in response to a prompt on the petition, “I am signing because...”. The name and location associated with each comment were removed prior to analysis. The comments were randomised with a random number generator in Microsoft Excel and sorting into ascending order, and 10% of the dataset (2000 comments) was randomly selected for analysis.

Analysis

Content analysis combines both qualitative and quantitative methods, allowing both the frequency of categories to be reported, as well as the content (21). Content analysis is an appropriate research method for scrutinising text data (22). It is also frequently used to analyse social media comments (23, 24). A large body of work has used this method to systematically categorise and quantify content in a dataset into frames and codes (25-27). A code is a pre-defined category which conveys a key component of the comment.

The analysis represents the perspective of psychological health researchers and epidemiologists. HO first became familiar with the content of the comments by reading through the comments and

making note of recurring themes. After an initial coding scheme was discussed with all authors and evaluated to have appropriate inter-rater reliability (i.e. Kappa >0.8), it was further refined resulting in 19 categories. Two authors then applied the coding scheme to the final selection of 2000 random comments. Each comment was allocated up to six codes based on its content. HO coded all 2000 comments and RD coded 10% (200) of these comments. Cohen's Kappa was calculated using IBM SPSS Statistics, version 21. Cohen's Kappa of 0.95 was achieved between the two coders, indicating "nearly perfect" agreement (28).

Descriptive statistical analysis was used to assess the frequency of each code. The codes were synthesised into four main themes through discussion with all authors once code frequency had been established.

RESULTS

From a sample of 2000 comments, four main themes emerged from content analysis – 1. valuing women's health and rights; 2. political statements; 3. cost and health care funding; 4. opposition to specific components of the screening program changes (e.g. interval and age of onset of screening). The codes encompassed in each theme are outlined in Table 1 with example quotes. Examples of health professional opposition were also noted.

Qualitative analysis: themes arising in comments

Valuing women's health and rights

The most frequently coded statements (32.6%) implied that the changes to the cervical screening program would de-value and threaten women's health. This was demonstrated by comments such as, "The Pap smear program is important for women's health", "Women matter", "I want to see my daughters and grand-daughters growing up healthy" and "Women have the right to be healthy". Twenty-two percent of commenters argued from personal experience in opposing the changes, because they or somebody they knew had experienced cervical cancer or pre-cancerous cervical lesions. Gender issues were discussed in 7.6% of comments, expressing opposition to men making decisions related to women's health, for example, "If men had periods and needed Pap smears, the tests would be free and be the best in the world".

Political issues

Comments expressed that the current Prime Minister and government were putting women's health at risk (13.6%). Comments included, "This government doesn't care about female reproductive health!", "The government is going too far this time", and, "I expected more from Malcolm Turnbull". Many comments also connected to the concept of gender, expressing the view that these changes would not be occurring if the Australian Prime Minister was a woman, if there were more female members of Parliament or if the Prime Minister had personally known someone affected by cervical cancer. Some comments included, "I think it really reflects that we need more women in decision-

making”, “If Malcolm [Turnbull] had a cervix these changes wouldn’t be happening” and, “Why does the government get to make these decisions, they are mostly men”.

Cost and health care funding

Ten percent of commenters believed that the changes to the cervical screening program were a ‘cost-cutting exercise’, part of ‘budget cuts’, and that money was being ‘taken’ from women’s health (9.9%). Almost 6% of comments conveyed the importance of maintaining funding for health care in general, for example, “Lives are more important than money”. Many expressed the importance of ensuring that health care and Pap smears should remain affordable and accessible to all women, for example, “Without government funding, some women won’t be able to afford two-yearly testing”. Others argued that while these changes to cervical screening may save money in the short-term, they would increase government costs in the long-term, due to subsequent increased cases of cervical cancer and increased treatment costs. An example includes, “The rates in cervical cancers will undoubtedly rise and end up costing more to treat an easily screened disease” (3.7%).

Opposition to specific changes

Change to the screening interval from two- to five-yearly was the most frequently expressed specific concern (16.7%). Comments included, “Five years between tests is too long to prevent cervical cancer developing to an advanced stage”. Opposition to increased age of first screening invitation was expressed in 9.1% of comments, including, “Women should be tested earlier, not later”, and “25 is too old to start screening”. Notably, only 2.6% of comments expressed hesitation with the HPV test itself. Comments opposing the HPV test included, “limiting the test to only screen for HPV induced cancers will put a greater number of lives at risk”, and discussed that not all cervical cancers were caused by HPV, or that HPV testing is not as thorough as cytology. Just under five percent of comments expressed confidence in the current program and argued that, “if something is not broken, don’t fix it”. Some commenters felt that the changes had not been communicated well, stating, “I think modifications to the testing should be thoroughly consulted across our community” and, “I don’t think the explanation is very clear regarding the changes”.

Health professional opposition

While not occurring frequently enough to be included in the coding scheme, some commenters expressed worry about the changes because their healthcare practitioner (GP or gynaecologist) did not support the changes. Three noteworthy comments were from people who identified themselves as GPs and one from a cytologist who commented that they had seen HPV negative tests with an abnormal Pap smear, that five years was too long an interval and that they had seen cases of cervical cancer in women younger than 25.

Table 1: Frequency of the 19 codes in a random sample of 2000 comments made in response to the petition

| Code description | Example | % |
|--|---|-------------|
| Theme 1: Valuing women's health, gender and women's rights | | 82.4 |
| Valuing women's health and valuing women* | "Every woman matters"; "I have three daughters and I want them to be healthy" | 32.6 |
| Personal or family/friend experience with cervical cancer/pre-cancerous lesion/other cancers | "I have friends who had cancerous and pre-cancerous cells on routine Pap smears BEFORE age 25."; "I had an abnormal Pap smear result at 23, it could've been cancer by 24 and under these new changes I wouldn't have known until I was 25!?" | 22.0 |
| Support for principles of disease prevention/early detection | "Prevention is better than cure!" | 14.1 |
| Gender and males making decisions for/about females and women's health | "Why should a man, who will never get cervical cancer, decide my fate"; "Time to let women have control, choice and safety over their own bodies!" | 7.6 |
| Right/entitlement of women to health care/Pap smears | "As women and taxpayers, we have a right to full health care" | 4.2 |
| A step backwards/policy regression | "This is a huge step backwards for women's rights" | 1.9 |
| Theme 2: Political statements | | 13.6 |
| Political, encompassing: Comments against the Prime Minister, the Liberal party; government as a whole | "The government is going too far this time"; "The amount of money the government waste on things of little to no importance and then to cut back on something as important as this just doesn't make sense" | 13.6 |
| Theme 3: Cost and health care funding concerns | | 19.3 |
| Cost cutting | "This is just another government cost-cutting exercise" | 9.9 |
| Access to health services: health care funding and affordability of tests | "Healthcare should be free in the lucky country"; "It is vital that Pap smears are affordable to all women" | 5.7 |
| Early detection will save money in the long run | "The government think they are saving money with this program, but they don't think of the financial burden on the health care system when there is an increasing in women's cancers as a result" | 3.7 |
| Theme 4: Opposition to specific components of screening program changes | | 36.2 |
| Opposition to extended (5 yearly) screening interval | "Five years is far too long between tests" | 16.7 |
| Concern about missing cancer cases in young women (<25 years of age) | "Young woman under the age of 20 can still get this cancer – 25 is too late!" | 9.1 |
| Concern about missing cancer cases in older women (>74 years of age) or fear of ageism | "After 74 you don't matter?" | 1.6 |
| Preference for the status quo | "I believe the conventional Pap smear screening is a great preventative program" | 4.7 |
| Disagreement with HPV test itself | "Not all cervical cancers are caused by HPV" | 2.6 |
| Sexual activity – age of first invitation to screen should be dependent on age of sexual activity or should generally be earlier due to earlier age of sexual activity | "Pap smears should be available from when sexual activity starts as most young girls these days are having sex very young" | 1.5 |
| No specific reason stated | | 10.4 |
| No reason stated for opposition | "This is important" | 5.7 |
| Emotional response, with no further reason for opposition stated | "This is disgusting"; "I don't want to die" | 3.9 |

*Valuing women's health was a code used in conjunction with other codes 70.2% of the time. The most frequent codes used in conjunction were (in order of frequency): disease prevention/early detection (9.5%), cost cutting (9.4%), politics (8.6%), concern about screening interval (7.7%), right/entitlement (6.0%) and gender (5.5%)

DISCUSSION

This study presents comments and concerns about the 2017 changes to the Australian NCSP expressed by one of Australia’s largest petitions on “Change.org”. Many comments about women’s health, politics and cost displayed significant misconceptions and misinformation about the rationale for the screening changes. Underpinning most comments in these themes was the idea that under the renewed screening program, an increased number of cervical cancers would be missed or diagnosed at an advanced stage, and that the rationale for changes was based on reducing government healthcare costs. Many commenters voiced concerns about the increased screening interval (from two to five years) and the later age of onset of screening (from 18 or 20 to 25 years of age). We noted a lack of opposition to a change from Pap smears to HPV testing itself. This may be reflective of the information and education material provided to the community in promoting the change, which focused on explaining HPV, or reflective of the lack of understanding regarding the differences between cytology and HPV testing that lead to the changes in screening interval and age (29). Another contributing factor to the significant opposition may have been news media coverage, which highlighted safety concerns expressed by opposing government ministers and community members about increased screening intervals and later age of screening onset (19, 30, 31).

Previous studies conducted in Australia prior to the announcement of the changes have identified women’s concerns about age of first invitation to screen, screening intervals and cost-cutting, so these issues could have been addressed in advance through better communication (32-34). A potential for cancer to be missed and a suspicion that an increased screening interval was related to cost were major concerns for women described in these publications, and are concerns shared by many commenters in our study. Internationally, publications similarly report that while HPV testing is generally accepted by women, longer screening intervals face opposition (35). It is therefore essential to educate women about the rationale for the change to screening intervals and age of first invitation to screen, namely the increased sensitivity of the HPV test and the harms of over-diagnosis and overtreatment.

Increasingly, these concerns are relayed over social media, as shown by a similar “Change.org” petition in the UK attracting over 300,000 signatures in January 2017 (36). While the petition was focussed on early screening options for symptomatic or high-risk groups, many comments expressed that cervical screening should be available from age 18 for all women. Concerns about increased screening intervals have also been raised by consumers in relation to other cancer types. In the US, recommendations for later starting age of breast cancer screening and prolonged screening intervals attracted public accusations that the new proposals were politically motivated and ‘anti-woman’ (37, 38).

Opposition to the screening changes may reflect status quo bias, and general opposition of people to change (39). A significant challenge is how to present a new screening program with major

changes so that confidence in the current program is not undermined. Patients and the public often hold the view that 'more is better' in medical care (40). This is because many patients have been socialised to fear rare, life-threatening events (41), and hold fatalistic views of cancer (42). Patients also have a widespread enthusiasm for cancer screening, reflecting a lay logic that prevention and early diagnosis is universally beneficial, which is not always the case (43). The relationship between sensitivity and specificity of screening tests is a difficult concept to communicate, and public health practitioners in the past have mainly focused on sensitivity in promoting screening to the public (44). We believe much greater efforts are required by public health practitioners to better educate the public about the relative benefits and harms of screening.

There are discrepancies between benefits to the public and benefits to the individual from cancer screening. Personal experience of illness tends to be far more salient for patients than general notions of healthcare spending for society as a whole (45). Public information from government websites regarding the changes have also mentioned the harmful effects of the current Pap smear screening program, for example treatments for abnormal cells which can lead to increases in premature birth (29). While this approach is more effective than discussing collective waste in communicating low-value care to patients, most healthy patients still have difficulty envisioning how screening could be harmful to them (46). Our recommendations for issues to address with patients concerned about the changes are outlined in Table 2.

Table 2: Recommended evidence for healthcare practitioners to address with patients concerned about Cervical Screening Program changes

| Concerns expressed in online petition | Evidence-based responses to concerns |
|--|---|
| Concerns about the sensitivity of HPV testing | HPV testing has increased sensitivity compared to Pap smear testing (8) and so has the potential to detect more cervical abnormalities than cytology-based screening. |
| Concerns about five-yearly screening interval | Increased sensitivity of the new HPV screening test compared to cytology to detect pre-cancerous cervical abnormalities and cervical cancer means that screening can be less frequent while still detecting almost all cervical abnormalities (8). Risk of cervical abnormalities over five years is lower for a HPV negative finding than a negative result from cytology over a two or three year interval. HPV testing can identify women at risk often before cell changes occur, whereas Pap smears detect changes to cervical cells after they have occurred. |
| Concerns about later age of first invitation to screen (25, as opposed to 18 previously) | Most cervical abnormalities in women under the age of 25 tend to regress by themselves, so testing early may lead to unnecessary invasive procedures (10). In women under 25, the harms are likely to outweigh the benefits of screening (e.g. unnecessary invasive procedures that can cause complications) and starting screening at 25 will reduce the number of investigations in this younger age group. Incidence and mortality of cervical cancer in women under 25 is very |

| | |
|--|---|
| | low and this has not changed since the introduction of the screening program (3). Young women are also offered the HPV vaccination and this is expected to lead to a significant reduction in the risk of cervical cancer in this age group. |
|--|---|

Despite the initial announcement of the changes by the Australian government in April 2014, the changes did not garner significant publicity until 2017. The rollout of the renewed NCSP was planned for May 2017, but has been delayed until December, as a component of the renewed program, the National Cancer Screening Register, was not ready for implementation. An implementation phase was to be undertaken which included engaging with the public to assess acceptability and educating clinicians and women about the changes (47). A summary of the Medical Services Advisory Committee application for NCSP changes described limited community consultation through 2012-2013 (48). Feedback was sought from, “clinical service providers, pathology service providers, consumers, professional bodies for health professionals and pathologists, and industry”, but results of these consultations are not described. While limited education has been provided to GPs through research initiatives such as the Compass trial in Victoria (49), and online education modules for clinicians were released in late 2017 (50), a 2015 article in the Australian Doctor magazine reported that “very little information has been distributed to GPs [about the changes]” (51). Ideally, clinicians would be an important group to engage and educate the public about cervical screening. The Australian Government website outlining the cervical screening changes encourages women to speak with health professionals about any concerns (29). A 2016 systematic review of 35 publications demonstrated that healthcare provider recommendation was positively correlated with improved screening rates (52).

To the best of our knowledge, this is the first study to analyse reasons in the wider population for opposition to the 2017 Australian cervical screening changes since their announcement and public discussion. The study is based on 2,000 randomly selected original comments from a sample of almost 20,000, and comments were on average 22 words long, providing sufficient detail to identify reasons for opposition. The importance and reach of the petition can be estimated by subsequent responses to it from the President of the Australian Medical Association, the Australian Government Minister for Health and Australia’s Chief Medical Officer (18).

It could be argued that these commenters are not representative of the majority of Australian women, but simply a vocal minority. However, this petition was one of the biggest petitions on “Change.org” in 2016 and 2017, indicating high public interest. Evidence supports the notion that public information exposure through social media has tangible impacts on health practices (53). Although the comments may not be representative of the majority of Australian women, we cannot disregard the impact that public opposition such as this can have on changes to public policy, for example where the recommendations for changing the US breast screening program received such

a backlash that the US Preventive Services Task Force was forced to reword the recommendations (37, 38). The strong views of a minority of vocal community members can be very powerful in the area of cancer screening.

Nevertheless, a limitation of this study is the absence of demographic information about petitioners, including age, gender and ethnicity. It is therefore unknown whether this sample represents women or men with lower, average or higher health literacy or educational status. If this is the case, more appropriate information targeting this demographic is required. However, it is more likely that the petition attracted responses from persons with a greater interest in health policy or women's health and may also represent a group with increased personal or family history of cervical cancer (37). It should also be noted that three commenters (<1%) self-identified as health care providers opposed to the changes, which may indicate that concern is spread across socio-economic and educational status, and that there is a need to address both professional and public concerns.

This study has practical and international implications for informing the significant challenge of rolling out future screening program changes, in particular, changing from cytology to HPV-based cervical cancer screening. It highlights the importance of effective communication to the public, of changes which involve longer screening intervals, later age of first invitation to screen and change in screening technology. Developing an understanding of the public's awareness of the benefits and harms of screening is crucial in the development of information about these changes.

Communication must acknowledge emotions involved in this screening change, should anticipate the public's known concerns, and must engage them in the decision-making process of screening changes. Future research will explore the optimum time to involve the public in screening policy. If the public is "misinformed and misguided", as suggested by the President of the Australian Medical Association in opposing the renewed cervical screening program, then this could be seen as a reflection of a failure to effectively communicate the changes and their rationale (18). GPs, gynaecologists and other health-care professionals who will discuss cervical screening with patients should be aware of public concern, and be prepared to discuss the reasons for the change in technology from cytology to HPV testing which result in the longer screening interval and older starting age to screening..

Supplement – The petition - Stop May 1st Changes to Pap Smears - Save Women's Lives

Early detection and regular pap smears are key to preventing and treating women with cervical cancer.

This effects you. Whether you are a woman or you have a mother, sister, aunty or grandmother. May 1st will see changes that will put women's lives at risk but save the government money.

As of May 1st the following changes will be implemented to women's Pap Smears:

"-women will be invited when they are due to participate via the National Cancer Screening Register

-the time between tests will change from two to five years

-the age at which screening starts will increase from 18 years to 25 years

-women aged 70 to 74 years will be invited to have an exit test.

The new program will commence from 1 May 2017 when the new Cervical Screening Test will become available on the Medicare Benefits Schedule. Until this time, women aged between 18 and 69 years who have ever been sexually active, should continue to have Pap test when due."

The government run website states that:

"Based on new evidence and better technology, the National Cervical Screening Program will change from 1 May 2017 to improve early detection and save more lives."

How can there be early detection when the time between pap smears has been extended by 3 years? And the age to begin pap smears is raised to the age of 25?

If you think you are immune to cervical cancer because you are too young - think again. Today the nurse at my doctors surgery told me that she did the pap smear of a young women in her early 20s who was diagnosed with cervical cancer. The cervical cancer she had was a type that will NOT be tested for after May 1. It was NOT caused by the HPV Virus. This young girl was forced to return from an overseas holiday for immediate treatment and died within 6 months.

Prior to May 1 the website advises:

"It is very important that women continue to participate in the current two yearly Pap test program to ensure they are not at risk of developing cervical cancer.

Pap tests have already halved the incidence and mortality from cervical cancer since the introduction of the National Cervical Screening Program in 1991.

Women will be due for the first Cervical Screening Test two years after their last Pap test."

So why would the change be increased from every 2 to 5 years if it is still important to have this done?

The next extremely worrying point of the new smear will be the following:

"The new Cervical Screening Test detects human papillomavirus (HPV) infection, which is the first step in developing cervical cancer.

The procedure for collecting the sample for HPV testing is the same as the procedure for having a Pap smear. A Health Care Professional will still take a small sample of cells from the woman's cervix. The sample will be sent to a pathology laboratory for examination.

While the current Pap test can detect abnormal cell changes, the new Cervical Screening Test will detect the HPV infection that can cause the abnormal cell changes, prior to the development of cancer.

Persistent HPV infections can cause abnormal cell changes that may lead to cervical cancer.

However, this usually takes a long time, often more than 10 years."

This means that ONLY HPV caused cervical cancer will be detected. HPV infection only account for 80-85% of Cervical cancers.

WHAT ABOUT THE OTHER 15%?

Some of the reasoning behind the changes are:

" -cervical cancer in young women is rare (in both HPV vaccinated and unvaccinated women)

-despite screening women younger than 25 years of age for over 20 years there has been no change to the rates of cervical cancer or rates of death from cervical cancer in this age group

-investigating and treating common cervical abnormalities in young women that would usually resolve by themselves can increase the risk of pregnancy complications later in life

-the HPV vaccination has already been shown to reduce cervical abnormalities among women younger than 25 years of age and, in contrast to screening, is ultimately expected to reduce cervical cancer in this age group."

Woman have now become a statistic - stating that it is rare in younger woman is not good enough.

It still happens and early detection and prevention is better than a cure.

Please see petition updates and responses. Dr Michael Gannon has responded to the petition.

Manuscript: “It has saved thousands of lives, so why change it?” Content analysis of objections to Australian cervical screening program changes

Consolidated criteria for reporting qualitative studies (COREQ): 32-item checklist

Developed from:
Tong A, Sainsbury P, Craig J. Consolidated criteria for reporting qualitative research (COREQ): a 32-item checklist for interviews and focus groups. *International Journal for Quality in Health Care*. 2007. Volume 19, Number 6: pp. 349 – 357

| No. Item | Guide questions/description | Reported on Page # |
|--|--|---|
| Domain 1: Research team and reflexivity | | |
| <i>Personal Characteristics</i> | | |
| 1. Inter viewer/facilitator | Which author/s conducted the inter view or focus group? | Page 6 |
| 2. Credentials | What were the researcher’s credentials? E.g. PhD, MD | Page 6 |
| 3. Occupation | What was their occupation at the time of the study? | Page 6 |
| 4. Gender | Was the researcher male or female? | N/A |
| 5. Experience and training | What experience or training did the researcher have? | Page 6 |
| <i>Relationship with participants</i> | | |
| 6. Relationship established | Was a relationship established prior to study commencement? | N/A – no relationship between participants and researchers. |
| 7. Participant knowledge of the interviewer | What did the participants know about the researcher? e.g. personal goals, reasons for doing the research | N/A – no relationship between participants and researchers. |
| 8. Interviewer characteristics | What characteristics were reported about the inter viewer/facilitator? e.g. Bias, assumptions, reasons and interests in the research topic | N/A – no interviews conducted |

| | | |
|--|--|-------------------------------------|
| Domain 2: study design | | |
| <i>Theoretical framework</i> | | |
| 9. Methodological orientation and Theory | What methodological orientation was stated to underpin the study? e.g. grounded theory, discourse analysis, ethnography, phenomenology, content analysis | Page 5 and 6 |
| <i>Participant selection</i> | | |
| 10. Sampling | How were participants selected? e.g. purposive, convenience, consecutive, snowball | Page 5 |
| 11. Method of approach | How were participants approached? e.g. face-to-face, telephone, mail, email | Page 5 |
| 12. Sample size | How many participants were in the study? | Page 5 |
| 13. Non-participation | How many people refused to participate or dropped out? Reasons? | N/A – no non-participants |
| <i>Setting</i> | | |
| 14. Setting of data collection | Where was the data collected? e.g. home, clinic, workplace | Page 5 |
| 15. Presence of non-participants | Was anyone else present besides the participants and researchers? | N/A – using existing online dataset |
| 16. Description of sample | What are the important characteristics of the sample? e.g. demographic data, date | Page 11 |
| <i>Data collection</i> | | |
| 17. Interview guide | Were questions, prompts, guides provided by the authors? Was it pilot tested? | N/A – no interviews conducted |
| 18. Repeat interviews | Were repeat inter views carried out? If yes, how many? | N/A – no interviews conducted |
| 19. Audio/visual recording | Did the research use audio or visual recording to collect the data? | N/A – no interviews conducted |
| 20. Field notes | Were field notes made during and/or after the inter view or focus group? | Page 6 |
| 21. Duration | What was the duration of the inter views or focus group? | Page 5 |
| 22. Data saturation | Was data saturation discussed? | Page 6 |
| 23. Transcripts returned | Were transcripts returned to participants for comment and/or correction? | N/A – no transcripts used |
| Domain 3: analysis and findings | | |
| <i>Data analysis</i> | | |

| | | |
|------------------------------------|---|--|
| | | |
| 24. Number of data coders | How many data coders coded the data? | Page 6 |
| 25. Description of the coding tree | Did authors provide a description of the coding tree? | Page 8 |
| 26. Derivation of themes | Were themes identified in advance or derived from the data? | Page 6 |
| 27. Software | What software, if applicable, was used to manage the data? | Page 6 |
| 28. Participant checking | Did participants provide feedback on the findings? | N/A – no participant contact with researchers, using existing online dataset |
| <i>Reporting</i> | | |
| 29. Quotations presented | Were participant quotations presented to illustrate the themes/findings? Was each quotation identified? e.g. participant number | Page 8 – quotations were not identified as per ethics approval |
| 30. Data and findings consistent | Was there consistency between the data presented and the findings? | From Page 6-12 |
| 31. Clarity of major themes | Were major themes clearly presented in the findings? | Page 8 |
| 32. Clarity of minor themes | Is there a description of diverse cases or discussion of minor themes? | Discussion of major and minor themes From page 6 to 12 |
